ABSTRACT

In the post-genomic era, most components of a cell are known and they can be quantified by large-scale functional genomics approaches. However, genome annotation is the bottleneck that hampers our understanding of living cells and organisms. Up-to-date functional annotation is of special importance for model organisms that provide a frame of reference for studies with other relevant organisms. We have generated a Wiki-type database for the Gram-positive model bacterium *Bacillus subtilis*, SubtiWiki (<http://subtiwiki.uni-goettingen.de/>). This Wiki is centered around the individual genes and gene products of *B. subtilis* and provides information on each aspect of gene function and expression as well as protein activity and its control. SubtiWiki is accompanied by two companion databases SubtiPathways and SubtIInteract that provide graphical representations of *B. subtilis* metabolism and its regulation and of protein–protein interactions, respectively. The diagrams of both databases are easily navigable using the popular Google maps API, and they are extensively linked with the SubtiWiki gene pages. Moreover, each gene/gene product was assigned to one or more functional categories and transcription factor regulons. Pages for the specific categories and regulons provide a rapid overview of functionally related genes/proteins. Today, SubtiWiki can be regarded as one of the most complete inventories of knowledge on a living organism in one single resource.

INTRODUCTION

The investigation of model organisms is a key element in the development of our understanding of biological processes. The availability of information on genes,

proteins and cellular processes in this handful of organisms is essential not only for the better understanding of these organisms, but also as a benchmark to study related organisms that may be more relevant with respect to medical or biotechnological aspects.

Bacillus subtilis is a well-characterized model organism for Gram-positive bacteria that include important pathogens such as *Bacillus anthracis*, *Listeria monocytogenes* or *Staphylococcus aureus*, as well as biotechnologically important species such as *Bacillus licheniformis* and the lactic acid bacteria. With the increasing amount of knowledge gained by functional genomics studies, *B. subtilis* is today one of the most advanced model organisms for systems biology approaches and is even considered as a potential host for synthetic modules. Due to the considerable importance of *B. subtilis*, a comprehensive and up-to-date source of information on the genes and proteins, their regulation, interactions and associated pathways is required, allowing the busy researcher to keep pace with the continuously accumulating data and knowledge.

In parallel to the first genome sequencing project (1), the SubtiList database was established and became very popular in the scientific community working with Gram-positive bacteria (2). Unfortunately, it has not been updated since 2005 and is no longer available since 2010. Recently, SubtiList was integrated into a larger database GenoList that aims at providing comprehensive information on multiple bacterial genomes (<http://genodb.pasteur.fr/cgi-bin/WebObjects/GenoList.woa/10/wa/goToTaxoRank?level=Bacillus%20subtilis%2020168>). In order to provide the community with up-to-date information, we created the Wiki-based data source SubtiWiki (3,4). The decision to make use of a Wiki was based on the experience that a database run by a single institution might no longer be updated if the focus of that institution changes. To the Wiki, each qualified scientist can contribute, thus the combined knowledge of the *Bacillus* community can be collected and made accessible to anyone interested in any specific aspect related to *B. subtilis* and other Gram-positive bacteria.

Gene name: sinR
Synonyms: sin, ffaD
Essential: no
Product: transcriptional regulator of post-exponential-phase responses genes
Function: control of biofilm formation

Interactions involving this protein in SubtiInteract: SinR
Metabolic function and regulation of this protein in SubtiPathways: Biofilm, Central C-metabolism, Protein secretion

MW, pI: 12 kDa, 7.177
Gene length, protein length: 333 bp, 111 aa
Immediate neighbours: sinR, tsA4

Get the DNA and protein sequences (Barbe et al., 2009)

Genetic context: A diagram showing the genomic context of the sinR gene, including its location on the chromosome, regulatory elements like sigma factors (σH, σS), promoters (PsinR, PtsA4), and other nearby genes (yogH, tsA4, tsB4, tsC4, tsD4).

Figure 1. The *sinR* gene page in *SubtiWiki*. Pages for each gene of *B. subtilis* exist in *SubtiWiki*. Background information on the gene (A) and protein (B) are given, as well as links to *SubtiPathways* and *SubtiInteract*. The bottom part of the pages displays community information and references (C) (Note that some publications have temporarily been left out for the purpose of this figure).

When *SubtiWiki* was created, it was the idea to collect all the information related to a gene/protein on a single page and provide this information with links to the relevant evidence (i.e. the PubMed entries). Moreover, the possibility to create internal links was used to facilitate the discovery of relations between different genes, proteins or RNAs (3). With the ongoing use and development of *SubtiWiki* it became obvious that it is well suited as a platform for different types of information. In a first attempt, graphical models of *B. subtilis* metabolic and regulatory pathways were created using CellDesigner in the Systems biology markup language (SBML) (5) and linked to the *SubtiWiki* pages. This resulted in a suite of graphical representations that is called *SubtiPathways* (4).

The access to the currently available knowledge in an appropriate form is pivotal to the interpretation of data from genome-scale experiments that are relevant to systems and synthetic biology. Therefore, *SubtiWiki* was further developed to support data mining approaches by providing a functional classification of the gene products of *B. subtilis* and a comprehensive collection of transcription factor regulons. These data sets are available in formats that are directly suitable for bioinformatic applications.

The genomic era and the initial phase of systems biology have provided us with lists of components that make up cells. Today, we can identify and quantify almost all molecules in a living cell, including proteins, RNA species and metabolites. However, only the interactions between these molecules make real life out of the components. In the past few years, these interactions came more and more into the focus of scientific research and also the *B. Subtilis* community spent a lot of efforts to elucidate protein–protein interactions (6–11). In its initial stage, *SubtiWiki* was focused on the individual components of the cell, and their interactions were just one aspect among many others. Given the great importance of protein–protein interactions we decided to accompany *SubtiWiki* by yet another project, *SubtiInteract*, which provides information on protein–protein interactions and that is again closely interconnected with *SubtiWiki*.

Due to the great importance of *B. Subtilis* as a model organism, additional initiatives have started to provide better functional annotation for this organism. Specifically, BsubCyc is part of the BioCyc collection of databases (12). According to the authors, BsubCyc is moderately curated. Moreover, a second Wiki for *B. Subtilis*, SubtilisWiki, has recently been set up which is still in its initial stage.

Figure 1. Continued.

In this work, we describe the current state of *SubtiWiki* with special emphasis on the new features: (i) the functional classification of the *B. subtilis* gene products, (ii) the compilation and implementation of transcription factor regulons and (iii) *SubtIInteract* for the visualization of protein–protein interaction networks in *B. subtilis*.

The key feature of *SubtiWiki*: the pages for individual genes and proteins

In *SubtiWiki*, there is an individual page for each gene that provides all the information on both the gene and its product, usually a protein, sometimes an RNA. In the original version of *SubtiWiki*, these pages could be retrieved by the gene designation. To take account of changing gene names and the fact that not every user

might be familiar with these names, the pages can now also be accessed using a fixed identifier, the so-called locus tag that was given to each gene or genetic feature when the *B. subtilis* genome was annotated (1, 13).

An example of a *SubtiWiki* gene page is shown in Figure 1. At the top of each page, the contents and a table with the most important information are shown. This table covers the gene name and synonym designations, the gene product and its function, the molecular weight and isoelectric point of the protein, the gene and protein lengths and the names of the adjacent genes. Moreover, the table contains links to the relevant representations of protein–protein interactions and to the pathway diagrams. Finally, the DNA and protein sequences can be downloaded and a diagram of the genomic context is shown.

Figure 1. Continued.

Below the table, the functional categories and regulons for the gene/protein are shown (see below). This allows immediate access to all related genes or proteins that are members of the same category or regulon. In the case of transcription regulators, a link to the page dedicated to the regulon controlled by the regulatory protein is provided.

The next section contains the information about the gene. It covers basic information as the unique identifier (locus tag), phenotypes of a mutant and gene-specific database entries. The largest section of each page is devoted to the encoded protein. It provides information on the biological activity of the protein, the protein family and possible paralogs. Moreover, kinetic data (if available), as well as information on protein domains, modifications, co-factors, effectors, interactions and the localization are presented. As for the gene section, the section for the protein is concluded with database links, such as structure databases (e. g. PDB), Uniprot or KEGG entries, as well as the E.C. numbers.

The following section of the page provides information on the expression of the gene and its regulation. This includes the operon structure, the sigma factor, transcription factors and their mode of action. At the bottom of the page, there is some community related information

(biological materials, labs working on the gene/protein), as well as a collection of references on all aspects of the gene/protein.

New features of *SubtiWiki*: the functional classification of the *B. subtilis* gene products and a comprehensive collection of transcription factor regulons

The current version of *SubtiWiki* describes the relatedness between the individual genes also by assigning common functional and regulatory properties. To this end, we first established a systematic functional classification of the *B. subtilis* gene products which is described in detail in the next paragraph. Second, we compiled the transcription factor regulons by collecting and manually curating information from DBTBS (14), a database of published transcriptional regulation events in *B. subtilis*. In addition, information on regulation was manually extracted from the recent literature. With respect to the target genes of individual transcription factors, we consulted scientists with expertise in specific fields of *B. subtilis* transcriptional regulation.

A first functional classification scheme was applied to all protein coding genes of *B. subtilis* (15) after completion of the genome sequence (1) and implemented into the SubtiList database (2). This scheme was adapted from a

The screenshot shows the SubtiWiki page for the SinR regulon. At the top, there's a navigation bar with links for 'page', 'discussion', 'view source', and 'history'. A 'Log in' button is also present. On the left, there's a sidebar with a 'SubtiWiki' logo, a search bar, and a 'toolbox' section containing links like 'What links here', 'Recent changes', and 'Special pages'. The main content area starts with a 'Contents [hide]' section, followed by a 'Genes in this regulon' section which lists numerous genes: *aprE*, *aprF*, *epsA*-*epsB*-*epsC*-*epsD*-*epsE*-*epsF*-*epsG*-*epsH*-*epsI*-*epsK*-*epsL*-*epsM*-*epsN*-*epsO*, *ltaA*-*ltaB*-*ltaC*, *rapG*, *rok*, *sigE*, *sigF*, *sigG*, *sigR*, *spolIAA-spolIAB*, *spolIAG*, *spolIVG*, *spaP*-*spaW*-*spaS*, *yvgN*, and *ywbD*. Below this is a 'Related SubtiWiki pages' section with a link to 'biofilm formation'. The next section is 'Important publications on the SinR regulon', featuring a green box with a citation: 'Frances Chu, Daniel B Kearns, Steven S Branda, Roberto Kolter, Richard Losick. Targets of the master regulator of biofilm formation in *Bacillus subtilis*. Mol. Microbiol. 2006, 59(4), 1216-28. [PubMed:16430695] [DOI: 10.1111/j.1365-2958.2006.05781.x]'. At the bottom, there's a 'Back to regulons' link, a 'Contributors' section with 'Jstuek, Lflorez', and a footer with links to 'Privacy policy', 'About SubtiWiki', and 'Disclaimers'. The bottom navigation bar includes a search field with 'sinR', a 'Find' button, and links for 'Next', 'Previous', 'Highlight all', and 'Match case'.

Figure 2. Page on the SinR regulon in *SubtiWiki*. Regulon pages give an overview of all the genes that are regulated by a specific transcription factor. Additional links lead to related *SubtiWiki* pages and to publications connected to the chosen regulon. An overview of all regulons is available at *SubtiWiki* or Excel file.

classification originally devised for *Escherichia coli* (16). However, in recent years it became apparent that the functional classification from SubtiList was no longer adequate because, (i) functions had been assigned to many ‘y-genes’ since the last update in 2002, (ii) the new *B. subtilis* genome sequence and annotation (13) introduced around 200 new genes, either newly annotated or resulting from fusions or fissions of previously existing genes and (iii) the classification scheme allowed each gene to be assigned only to a single annotation term. As for the majority of the gene products, the physiological role cannot be sufficiently described by a single functional category (17), more advanced functional classification schemes for bacterial species have been developed that permit the assignment of multiple categories to one gene product and also possess a higher specificity through several layers of subcategories (18,19). Consequently, a new functional classification for the *B. subtilis* gene products has been devised and implemented in *SubtiWiki*. This classification is organized in a hierarchical, tree-like structure with six main categories that are subdivided in up to four levels of increasing specificity. Five of the main categories cover all main aspects of the life of a prokaryotic organism: Cellular Processes, Metabolism, Information Processing, Lifestyles and Prophages and Mobile Genetic Elements. A last main category, Groups of Genes, assembles the genes/proteins

based on the level of knowledge on the function, the localization and the nature of the gene product. This classification scheme is organism-independent and therefore, generally suitable for the systematic classification of protein function in bacteria. In line with this, the main category ‘Lifestyles’ covers species-specific functions and could be readily adapted to other organisms. With respect to the specificity of the subcategories, the classification scheme was designed to ensure the same level of detail at a certain sublevel; for example, all individual metabolic pathways (e.g. biosynthesis of amino acids or cell wall components) are classified as fourth level categories.

As mentioned above, the information about the cellular function (categories) and transcriptional regulation (regulons) is implemented in the *SubtiWiki* pages in two fields in the upper part of the gene pages: ‘Categories containing this gene/protein’ and ‘The gene is member of the following regulons’ (Figure 1). The respective categories and regulons are clickable, leading to the pages listing all category members at the third level of the classification and all regulon members, respectively (Figures 2 and 3). In the case of the functional categories, the corresponding main category and the directly higher-level category are displayed as ‘Parent categories’ and the other categories in the same branch of the tree as ‘Neighbouring Categories’ (Figure 3). Relevant publications are listed in the bottom part of the category and regulon pages, respectively.

Figure 3. Page for the category ‘Biofilm formation’ in *SubtiWiki*. All genes in the database are assigned to one or several functional categories. The main categories are divided into subcategories like Biofilm formation (part of the main category Lifestyles). The category pages list all the genes and operons that are involved in the given process, as well as links to key publications (not displayed).

Overviews on all categories and regulons can be accessed from each *SubtiWiki* gene page.

Importantly, the functional and regulatory properties of a given gene are displayed together on the respective *SubtiWiki* gene page, thus providing an additional level of insight into the physiological role of a gene/protein of interest. For the first time, this compilation puts the claim of the ‘omics’ technologies, to provide information for discovering novel relationships into reality. As an example, the *YxjG* protein could be assigned as a putative methionine synthase based on the regulation that the *yxjG* gene shares with all other genes involved in methionine biosynthesis (20). Moreover, with the regulon gene lists and functional categories, it is now possible to directly access all genes/proteins that are related to each other by function, localization or regulation and to get a quick overview on any functional and regulatory aspect of *B. subtilis*.

As for the other content of *SubtiWiki*, the newly added types of information require regular updates, because the functional annotation of gene products, in particular those of so far unknown function, is continuously updated as more information is becoming available, which then also leads to the assignment to new or additional functional categories. The same holds true for the assignment of genes to transcription factor regulons.

In order to meet the specific requirements of bioinformatics applications, regularly updated versions of the following files are available for download: (i) the functional classification scheme, (ii) a table listing all categories with their respective genes and (iii) a table with all regulons and their member genes. The functional and regulatory

classifications are extremely useful data sources for the analysis and interpretation of genome-scale experiments. First, they allow for data mining approaches such as functional profiling which use various kinds of prior knowledge for statistical enrichment analysis to infer physiological context of a list of genes or proteins. In addition, genome-scale experimental data can be visualized by displaying them on a functional classification or transcriptional regulatory annotation. For example, in a proteomic and transcriptomic profiling study of glucose-starved *B. subtilis* cells (21), Voronoi treemaps linking a representation of hierarchically structured functional categories or gene regulatory information (regulon/operon/gene) with gene expression data were used to support the analysis of a complementary proteome and transcriptome data set. Information about transcription factor regulons was derived from *SubtiWiki*. Moreover, analyses facilitating the understanding of the metabolic and regulatory network organization, such as the prediction of new transcription factor target genes and assignment of putative functions to so far un-annotated genes, are also supported by the *SubtiWiki* functional classification and our compilation of transcription factor regulons.

SubtiPathways* and *SubtInteract*—two resources that complement *SubtiWiki

Three genome-scale models of *B. subtilis* integrate the existing knowledge into models of metabolic and regulatory networks (22–24). Since these models are not easily accessible for the lab scientist, we developed a suite of diagrams of metabolism and regulation in *B. subtilis*,

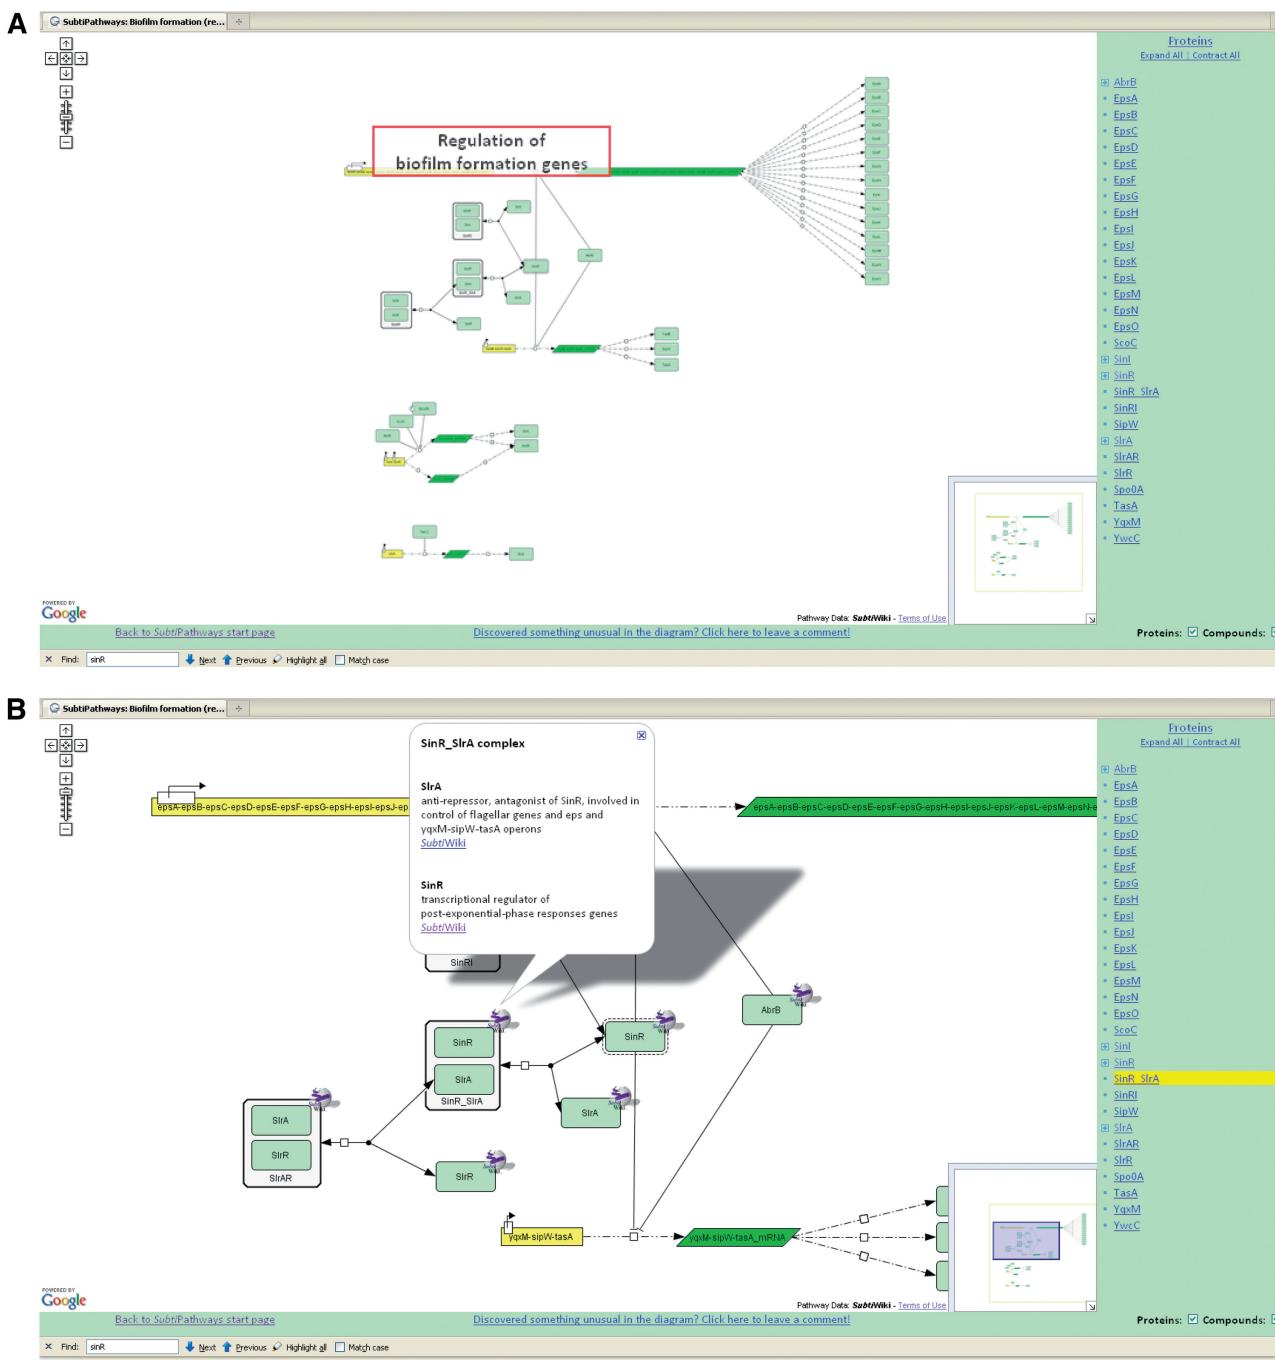

Figure 4. Representation of Biofilm formation in *SubtiPathways*. Diagrams are available for a broad range of metabolic pathways and cellular processes (A). A list of all involved genes is shown on the right side and the diagram itself shows gene expression and regulation. At the highest magnification, a zoom function reveals clickable elements (B) that provide information on the protein (e.g. 3D structure, links to other pathways and *SubtiWiki*).

SubtiPathways. The *SubtiPathways* diagrams provide an interface for systems biology as they link information relevant for modelers and bench biologists. Today, *SubtiPathways* encompasses 35 diagrams that cover different aspects of *B. subtilis* physiology and regulation (Figure 4). These diagrams are linked to the *SubtiWiki* pages of the relevant genes and, on the other hand, each

gene page contains a link to the specific diagram, if available.

Recently, we have focused on protein–protein interactions. First, we generated a genome-scale model of the interactions using Cytoscape (25). This interaction model was then converted into a navigatable diagram using the Google maps API and the program CellPublisher (26).

Figure 5. Global and specific presentations in SubtIInteract. The user interface allows a global view of protein interactions (A) with additional information on single proteins (e.g. SinR)-like protein structures and links to SubtiWiki or SubtiPathways. Furthermore, interaction partners of specified proteins can be shown with different network complexities (B).

As described for *SubtiPathways*, the diagram can be intuitively navigated (by zooming and panning). Moreover, each protein in the diagram is directly linked to the corresponding *SubtiWiki* page (Figure 5A). In addition, we used our database that collects all interactions to generate protein-specific pages that display the interactions of this particular protein. In the left side bar, the complexity of the network can be selected, whereas links to the *SubtiWiki* gene pages are provided in the side bar on the right (Figure 5B). By September 2011, *SubtInteract* contained 1830 interactions involving 801 proteins and 5 RNAs. The protein-specific interaction networks are directly accessible from the Table on the top of the gene pages (Figure 1A).

PERSPECTIVES

SubtiWiki (with *SubtiPathways* and *SubtInteract*) has become one of the most complete inventories of knowledge on a living organism in one single resource. Both the continuous updates and the novel features contribute to its popularity that is reflected by more than one million page visits during the last 12 months. In the same period, 48 genes were given new designations in the scientific literature, and these new gene names were also adopted for *SubtiWiki*. Moreover, for 40 genes of previously unknown function, a functional annotation was assigned during the last year.

In the future, keeping up-to-date with the state of research will remain a key task for the development of *SubtiWiki*. In addition, we will link *SubtiWiki* to global gene expression data in order to provide a new type of information that is at the heart of the interest of many *Bacillus* researchers.

ACKNOWLEDGEMENTS

We are grateful to Maximilian Fünfgeld for his help with the development of *SubtInteract*.
